Why Automate?

- ▶ Save time.
- ▶ Save money.
- ▶ Computers don't get bored.
    - ▶ Testing is boring work.
- ▶ Doesn't overlook test cases.

Automated Testing

○○○○

How Do You Automate?

- Write functions that exercise the system under test.
- Put these functions in a format that can be consumed by a test runner.
- Call test runner.
- Interpret test runner's output.

Kinds of Test Automation

- ▶ Unit- Verify individual code functions work as expected.

- ▶ Integration- Verify modules are working together.

- ▶ Regression- Verify stuff that worked isn't broken and stuff that's broken before haven't broken again.

- ▶ Functional- Validate that system as a whole conforms to requirements (eg, works to a user's eye).

- ▶ Many others- see CSE3411 & CSE4415.

Technologies

Languages

- ▶ *Unit frameworks (CUnit, JUnit, CppUnit, etc.) enable the practice, though they're useful for far more than unit testing.
- ▶ Testers are usually, unintuitively, **less** trained as programmers.
- ▶ Consequently, they prefer "easier" scripting languages like Python or Ruby.
- ▶ This discussion will center around Python. All of it can happen in Ruby.

Technologies

Frameworks

- ▶ Include a suite of assertion convenience methods, logging/reporting facilities, and a runner.
- ▶ Python: `unittest`, `nose`, `pytest`.
- ▶ `unittest` is in the Python Standard Library, we'll use it.

Technologies

Glass Box Testing

- ▶ Test code interacts directly with the program's source.
- ▶ Can probe quite deeply.
- ▶ Use mock interfaces shims to accomplish testing goals.
- ▶ Unit testing and integration testing are automated through Glass Box methods.

Technologies

Black Box Testing

▶ Test code interacts with the user (or some other non-transparent) interface into the running program.

▶ Use external toolkits like Selenium to enable driving user interfaces.

▶ Usually in a special test environment but otherwise the unmodified software.

▶ Regression testing and functional testing are automated through Black Box methods.

Technologies

Selenium

- ▶ Programmatic control of web browsers for testing and other automation.
- ▶ Driver class allows navigation (get this URL) and document queries (get this node for me to read from or click on or type into).
- ▶ Node class allows interaction (click here, type this), and data retrieval (What's the text body? What' site does this form POST to?) and limited Driver-like queries for children.

HTML (summary)

- XML- based documents for the web.
- Tree-structured.
- Nodes have properties, including text, in addition to children.

○○○○○○○○
○○○○

Technologies

CSS (summary)

- Language for styling HTML documents.
- Format- `selector: rule;`
- Selectors: strings that identify one, many, or none of the nodes in an HTML document.
- Rules: Specific styling rules to apply to each node matched by preceeding rule.

Patterns and Practices

Page Object Modeling

- ▶ Each page on a site corresponds to a Python class.
- ▶ Fields or text spots on pages get getters and setters.
- ▶ Clickable things get click() functions.
  - ▶ If the click should transition to a new page, construct and return that new page's class.
- ▶ In class consturctors, assert things that are constant about that page. Username in header? Some error message not in the body? Standard controls are present?

0000

What Traditional Testing Finds

- Known bugs, whether previously fixed or things that you look to see are working not working.
- Unfinished features. (Write the tests before you write the feature.)
- Clear and obvious program crashes.*
  - *Clear and obvious to the computer. Nonzero return codes.

How To Find What Traditional Testing Doesn't Find

- All the things we miss are failures of imagination. If you can imagine a scenario, you can probably write a test for that scenario.
- Computers are really bad at imagining things too, but they're decent at rolling dice.

Automated Testing

Examples of The Bugs We Want To Find

- ▶ What happens when you put 22 calls on hold on a digital phone system?
- ▶ What happens when you leave Atom running for four months while writing a thesis in it?
- ▶ What happens when 200k users log on to your system at the start of a workday?
- ▶ Other "hard to reproduce" failures.

Software as a State Machine

Software Is A State Machine

- Software can be represented as a machine with states, state transitions, inputs, outputs, and a few dozen other tuples.
- This IS the software, just a different way to view it.
- This is already sort of evident.

Automated Testing
○○○○○○○
○○
○○○

Long Sequence Testing in Yeager

○○○○○○○
○○○○○○○○○

High Volume Automated Testing
○○○○○○
○○○○
○○○○○○○
○○○○

Software as a State Machine

Testers Write Based On The System's States

- Page Object Model pattern emulates the state model, and includes state transitions.

- Resultant state model is significantly simplified compared to a formal model specification.

- Surprisingly detailed look at how the system is built.

Automated Testing
○○○○○○○
○○
○○○

○○○○○○○○
○○○○○○○○○○

High Volume Automated Testing
○○○○○○
○○○○
○○○○○○○○
○○○○

Software as a State Machine

State Models Can Help Us Plan New Tests

▶ Given a printout of a state model, it's not hard to trace a pen along the model and plan a new test sequence.

▶ It's also easy to see what parts are tested (covered) and what parts aren't yet tested (still not covered).

Automated Testing

○○○○○○○○
○○○○

Software as a State Machine

Context: What Simplified State Models Don't Capture

- Things you've typed into the program.
- Things the program read from some external source.
- Overheating CPUs, cosmic rays, etc.

Automated Testing

Software as a State Machine

Random Walks: Generating New Test Plans Automatically

- ▶ Given one of these simplified state models represented as a graph, and an RNG, it's not hard to generate new test plans.
- ▶ How many ways can you go from here? Ok, draw a random choice from that many. Go there. Repeat.
- ▶ That's the algorithm, by the way.

Automated Testing

○○○○

Software as a State Machine

What Bugs Look Like From A Modeling Perspective

- ▶ Places where the model says you should be able to go, and you are unable to go, are bugs.
- ▶ They might be bugs in the software.
- ▶ While you're learning the software under test, they're probably bugs in the model.

Automated Testing

Software as a State Machine

Prior Art: Model Based Testing

▶ Jonathan Jacky, in Radiation Oncology, of the University of Washington, made an excellent Python model-based tester called PyModel. Apparently there are model-capturable bugs in the field of Radiation Oncology. (Therac 25)

▶ It consumes a handcrafted model.

▶ It can emit a test plan that covers the whole model.

▶ It can emit a test plan that takes a random, should-be valid walk of the software under test.

Automated Testing

○○○○

Software as a State Machine

Weaknesses in PyModel

- ▶ It requires a handcrafted model in a finicky domain-specific language. Not Plain Old Python.
- ▶ It's really hard to get test plans to run as tests.
- ▶ It has a lot of overhead to get running.

Usage

What Is Yeager?

- ▶ Python module.
- ▶ Annotate funtions indicating that they cause a state transition.
- ▶ Infers a state model.
- ▶ Can take a random walk on that model.
- ▶ Has debug tools to understand the model you've made.

What Is High Volume Test Automation?

Tests that algorithmically generate, execute, evaluate, and summarize the results of arbitrarily many test actions on a system, in such volume as to:

1. Exceed the volume a reasonable testing staff could do manually.
2. Expose behaviors of the system not normally exposed during traditional testing techniques.
3. Simulate (ab)use of the system more realistically and dynamically than would be attainable through traditional techniques.
4. Generate test scenarios that are not outside the realm of possibility or even probability due to the high-availability nature of modern software systems.
